Overview of this Lecture

1 Introduction

2 Policy Performance Bounds

Introduction

Policy gradient algorithms try to solve the optimization problem

$$\max_{\theta} J(\theta) = \mathbb{E}_{\tau \sim \pi_{\theta}} \left[\sum_{t=0}^{\infty} \gamma^t r_{t+1} \right]$$

by taking stochastic gradient ascent on the policy parameters θ , using the policy gradient

$$\nabla_{\theta} J(\theta) = \mathbb{E}_{\pi_{\theta}} \left[\sum_{t=0}^{\infty} \nabla_{\theta} \log \pi_{\theta}(a_t | s_t) \Psi_t \right]$$

1. $\Psi_t = \gamma^t Q^{\pi_{\theta}}(s_t, a_t)$, State action value function
2. $\Psi_t = \gamma^t A^{\pi_{\theta}}(s_t, a_t) = \gamma^t [Q^{\pi_{\theta}}(s_t, a_t) - V^{\pi_{\theta}}(s_t)]$, Advantage function
3. $\Psi_t = \gamma^t [r_{t+1} + \gamma V^{\pi_{\theta}}(s_{t+1}) - V^{\pi_{\theta}}(s_t)]$, TD residual

Gradient of the performance measure is given by

$$\nabla_{\theta} J(\theta) = \mathbb{E}_{\pi_{\theta}} \left[\sum_{t=0}^{\infty} \nabla_{\theta} \log \pi_{\theta}(a_t | s_t) \Psi_t \right]$$

- ▶ Policy Gradient seen thus far is **on-policy**
- ▶ Gradient update is performed using samples collected from current policy
- ▶ Above formulation does not allow to recycle old data
- ▶ If we want to use samples from other policies, then the above gradient term needs correction using **importance sampling** weights

Importance Sampling in PG : Possible Remedy ?

What if we do not samples from π_θ instead samples are from π_η (i.e. $\tau \sim \pi_\eta$) ?

We can rewrite the gradient estimate as,

$$\nabla_\theta J(\theta) = \mathbb{E}_{\tau \sim \pi_\eta} \left[\frac{P(\tau|\pi_\theta)}{P(\tau|\pi_\eta)} \sum_{t=0}^{\infty} \nabla_\theta \log \pi_\theta(a_t|s_t) \Psi_t \right]$$

$$\frac{P(\tau|\pi_\theta)}{P(\tau|\pi_\eta)} = \frac{\mu(s_0) \prod_{t=0}^{\infty} P(s_{t+1}|s_t, a_t) \pi_\theta(a_t|s_t)}{\mu(s_0) \prod_{t=0}^{\infty} P(s_{t+1}|s_t, a_t) \pi_\eta(a_t|s_t)} = \prod_{t=0}^{\infty} \frac{\pi_\theta(a_t|s_t)}{\pi_\eta(a_t|s_t)}$$

Even for policies only slightly different from each other, many small differences multiply to become a big difference and IS weights can **explode** or **vanish**

Problem : How can we efficiently use samples from old policies while avoiding the challenges posed by importance sampling ?

- Policy gradient takes step in parameter space

$$\theta_{n+1} = \theta_n + \alpha \nabla_{\theta_n} J(\theta_n)$$

- **Distance** in parameter space \neq Distance in policy space
- Hard to get step size right as a result
- Example of a policy space : For finite state and action case, the policy space is given by

$$\Pi = \left\{ \pi : \pi \in \mathbb{R}^{|S| \times |A|}, \sum_a \pi_{sa} = 1, 0 \leq \pi_{sa} \leq 1 \right\}$$

The Step Size Issue

Policy Gradient algorithms perform stochastic gradient ascent

$$\theta_{k+1} = \theta_k + \alpha_k \hat{g}_k$$

with step $\Delta_k = \alpha_k \hat{g}_k$

- ▶ Step size is too large, performance collapse
 - ★ Consequences in RL setting is more severe than for supervised learning
- ▶ Step size is too low, slow progress

Difference in Policy Space : Discrete Case

Consider a family of policies with the following parametrization

$$\pi_{\theta}(a) = \begin{cases} \sigma(\theta), & \text{if } a = 1 \\ 1 - \sigma(\theta), & \text{if } a = 2 \end{cases}$$

Small changes in the policy parameters can unexpectedly lead to big changes in the policy

Difference in Policy Space : Continuous Case

- ▶ How to make use of data from old policy while avoiding challenges that arise from importance sampling ?
 - ★ At least use roll-outs from **most recent policy** as effectively as possible
- ▶ How to design an update rule that doesn't change the policy more than we intend to ?
 - ★ Take steps that respect notion of **distance in policy space** rather than in parameter space

Policy Performance Bounds

Recall that the performance of a policy π is given by

$$J(\pi) = V^{\pi}(s_0)$$

where $s_0 \in \mu(s)$ is the start state of the trajectory π

Relative Performance Identity of Two Policies

For any two policies π' and π_0 we have,

$$J(\pi') - J(\pi_0) = \mathbb{E}_{\tau \sim \pi'} \left[\gamma^t A^{\pi_0}(s_t, a_t) \right]$$

Proof of Relative Performance Identity of Two Policies

$$\begin{aligned} J(\pi') - J(\pi_0) &\stackrel{?}{=} \mathbb{E}_{\tau \sim \pi'} \left[\sum_{t=0}^{\infty} \gamma^t A^{\pi_0}(s_t, a_t) \right] \\ &= \mathbb{E}_{\tau \sim \pi'} \left[\sum_{t=0}^{\infty} \gamma^t [r_{t+1} + \gamma V^{\pi_0}(s_{t+1}) - V^{\pi_0}(s_t)] \right] \\ &= J(\pi') + \mathbb{E}_{\tau \sim \pi'} \left[\sum_{t=0}^{\infty} \gamma^{t+1} V^{\pi_0}(s_{t+1}) - \sum_{t=0}^{\infty} \gamma^t V^{\pi_0}(s_t) \right] \\ &= J(\pi') + \mathbb{E}_{\tau \sim \pi'} \left[\sum_{\substack{t=0 \\ t=1}}^{\infty} \gamma^t V^{\pi_0}(s_t) - \sum_{t=0}^{\infty} \gamma^t V^{\pi_0}(s_t) \right] \\ &= J(\pi') - \mathbb{E}_{\tau \sim \pi'} [V^{\pi_0}(s_0)] \\ &= J(\pi') - J(\pi_0) \end{aligned}$$

Can we use the identity,

$$J(\pi') - J(\pi_0) = \mathbb{E}_{\tau \sim \pi'} \left[\sum_{t=0}^{\infty} \gamma^t A^{\pi_0}(s_t, a_t) \right]$$

for policy improvement to go from **old policy** π_0 to **new policy** π' ?

$$\arg \max_{\pi'} J(\pi') = \arg \max_{\pi'} [J(\pi') - J(\pi_0)] = \arg \max_{\pi'} \left[\mathbb{E}_{\tau \sim \pi'} \left[\sum_{t=0}^{\infty} \gamma^t A^{\pi_0}(s_t, a_t) \right] \right]$$

- ▶ Define performance of π' in terms of advantages from π_0
- ▶ Problem : Still requires trajectories from π' !!

Discounted State Distribution

Define discounted future state distribution d^π for a state s as

$$d^\pi(s) = (1 - \gamma) \sum_{t=0}^{\infty} \gamma^t \mathbb{P}(s_t = s | \pi)$$

Consider the expectation

$$\mathbb{E}_{\tau \sim \pi} \left[\sum_{t=0}^{\infty} \gamma^t A^\pi(s_t, a_t) \right]$$

The above expectation can be rewritten using the discounted future state distribution d^π as

$$\frac{1}{1 - \gamma} \mathbb{E}_{\substack{s \sim d^\pi \\ a \sim \pi}} [A^\pi(s, a)]$$

That is,

$$\mathbb{E}_{\tau \sim \pi} \left[\sum_{t=0}^{\infty} \gamma^t A^\pi(s_t, a_t) \right] = \frac{1}{1 - \gamma} \mathbb{E}_{\substack{s \sim d^\pi \\ a \sim \pi}} [A^\pi(s, a)]$$

$$\begin{aligned} J(\pi') - J(\pi_0) &= \mathbb{E}_{\tau \sim \pi'} \left[\sum_{t=0}^{\infty} \gamma^t A^{\pi_0}(s_t, a_t) \right] \\ &= \frac{1}{1-\gamma} \mathbb{E}_{\substack{s \sim d^{\pi'} \\ a \sim \pi'}} [A^{\pi_0}(s, a)] \\ &= \frac{1}{1-\gamma} \mathbb{E}_{\substack{s \sim d^{\pi'} \\ a \sim \pi_0}} \left[\frac{\pi'(a|s)}{\pi_0(a|s)} A^{\pi_0}(s, a) \right] \end{aligned}$$

Only problem is $s \sim d^{\pi'}$!

Under what conditions is it OK to assume

$$\frac{1}{1-\gamma} \mathbb{E}_{\substack{s \sim d^{\pi'} \\ a \sim \pi_0}} \left[\frac{\pi'(a|s)}{\pi_0(a|s)} A^{\pi_0}(s, a) \right] \stackrel{?}{\approx} \frac{1}{1-\gamma} \mathbb{E}_{\substack{s \sim d^{\pi_0} \\ a \sim \pi_0}} \left[\frac{\pi'(a|s)}{\pi_0(a|s)} A^{\pi_0}(s, a) \right]$$

In other words, under what conditions can we have $d^{\pi'} \approx d^{\pi_0}$?

We can have $d^{\pi'} \approx d^{\pi_0}$, if π' and π_0 , are close !!

- ▶ Closeness is measured in terms of **KL divergence**
- ▶ If the policies are close in **KL divergence**, then the above approximation is good

For any two probability distributions P and Q $D_{KL}(P||Q)$ is defined as

$$D_{KL}(P||Q) = \sum_x P(x) \log \frac{P(x)}{Q(x)}$$

KL divergence has the following properties

- ▶ $D_{KL}(P||P) = 0$
- ▶ $D_{KL}(P||Q) \geq 0$
- ▶ $D_{KL}(P||Q) \neq D_{KL}(Q||P)$

KL divergence between policies π' and π_0 is given by

$$D_{KL}(\pi'||\pi_0)[s] = \sum_{a \in \mathcal{A}} \pi'(a|s) \log \frac{\pi'(a|s)}{\pi_0(a|s)}$$

Surrogate Loss Function

If policies π' and π_0 are 'close' in terms of their KL divergence, then,

$$\begin{aligned} J(\pi') - J(\pi_0) &= \frac{1}{1-\gamma} \mathbb{E}_{\substack{s \sim d^{\pi'} \\ a \sim \pi_0}} \left[\frac{\pi'(a|s)}{\pi_0(a|s)} A^{\pi_0}(s, a) \right] \\ &\approx \frac{1}{1-\gamma} \mathbb{E}_{\substack{s \sim d^{\pi_0} \\ a \sim \pi_0}} \left[\frac{\pi'(a|s)}{\pi_0(a|s)} A^{\pi_0}(s, a) \right] \\ &= \mathbb{E}_{\tau \sim \pi_0} \left[\sum_{t=0}^{\infty} \gamma^t \frac{\pi'(a_t|s_t)}{\pi_0(a_t|s_t)} A^{\pi_0}(s_t, a_t) \right] \end{aligned}$$

Define the quantity $\mathcal{L}_{\pi_0}(\pi')$ as the **surrogate loss function**, as,

$$\mathcal{L}_{\pi_0}(\pi') = \mathbb{E}_{\tau \sim \pi_0} \left[\sum_{t=0}^{\infty} \gamma^t \frac{\pi'(a_t|s_t)}{\pi_0(a_t|s_t)} A^{\pi_0}(s_t, a_t) \right]$$

► $J(\pi') - J(\pi_0) \approx \mathcal{L}_{\pi_0}(\pi')$

If policies π' and π_0 are 'close' in terms of their KL divergence, then,

$$J(\pi') - J(\pi_0) \approx \mathcal{L}_{\pi_0}(\pi')$$

We can have a **relative policy performance bound** using KL divergence as

$$\left[J(\pi') - (J(\pi_0) + \mathcal{L}_{\pi_0}(\pi')) \right] \leq C \sqrt{\mathbb{E}_{s \sim d^{\pi_0}} [D_{KL}(\pi' || \pi_0)[s]]}$$

where $C = \frac{4\varepsilon\gamma}{1-\gamma^2}\alpha^2$ with $\alpha = \max_{s \sim d^{\pi_0}} [D_{KL}(\pi' || \pi_0)[s]]$ and $\varepsilon = \max_{s,a} A^{\pi_0}(s, a)$

$$\mathcal{L}_{\pi_0}(\pi') = \mathbb{E}_{\tau \sim \pi_0} \left[\sum_{t=0}^{\infty} \gamma^t \frac{\pi'(a_t|s_t)}{\pi_0(a_t|s_t)} A^{\pi_0}(s_t, a_t) \right]$$

- ▶ $\mathcal{L}_{\pi_0}(\pi')$ is something that we can evaluate using samples from old policy π_0
- ▶ Importance sampling is used; but weights depends only on current time-step (not preceding history); hence importance sampling weights don't vanish or explode
- ▶ Let π_{θ_k} and π_{θ} be two parametrized policies. Then, $\nabla_{\theta} \mathcal{L}_{\pi_{\theta_k}}(\pi_{\theta})|_{\theta=\theta_k}$, is equal to the policy gradient

$$\begin{aligned} \nabla_{\theta} \mathcal{L}_{\pi_{\theta_k}}(\pi_{\theta})|_{\theta=\theta_k} &= \mathbb{E}_{\tau \sim \pi_{\theta_k}} \left[\sum_{t=0}^{\infty} \frac{\nabla_{\theta} \pi_{\theta}(a_t|s_t)|_{\theta=\theta_k}}{\pi_{\theta_k}(a_t|s_t)} \gamma^t A^{\pi_{\theta_k}}(s_t, a_t) \right] \\ &= \mathbb{E}_{\tau \sim \pi_{\theta_k}} \left[\sum_{t=0}^{\infty} \nabla_{\theta} \log(\pi_{\theta_k}(a_t|s_t))|_{\theta=\theta_k} \gamma^t A^{\pi_{\theta_k}}(s_t, a_t) \right] \end{aligned}$$

We can rewrite the relative policy performance bound equation as

$$[J(\pi') - J(\pi_0)] \geq \mathcal{L}_{\pi_0}(\pi') - C \sqrt{\mathbb{E}_{s \sim d^{\pi_0}} [D_{KL}(\pi' || \pi_0)[s]]}$$

Suppose π_{k+1} and π_k are related by

$$\pi_{k+1} = \arg \max_{\pi'} \left[\mathcal{L}_{\pi_k}(\pi') - C \sqrt{\mathbb{E}_{s \sim d^{\pi_k}} [D_{KL}(\pi' || \pi_k)[s]]} \right]$$

- ▶ Note π_k is a feasible point and the objective at π_k is equal to 0
 - ★ $\mathcal{L}_{\pi_k}(\pi_k) \propto \mathbb{E}[A^{\pi_k}(s_t, a_t)] = 0$
 - ★ $D_{KL}(\pi_k || \pi_k) = 0$
- ▶ \implies Optimal value ≥ 0
- ▶ By the performance bound inequality, we have $J(\pi_{k+1}) - J(\pi_k) \geq 0$

-
- 1: Initialize π_0
 - 2: **for** $k = 0, 1, 2, \dots$ until convergence **do**
 - 3: Sample a trajectory τ from policy π_k
 - 4: Compute advantage function $A^{\pi_{\theta_k}}(a_t, s_t)$ for all (s_t, a_t) pairs in the trajectory τ
 - 5: Solve the optimization problem

$$\pi_{k+1} = \arg \max_{\pi'} L_{\pi_k}(\pi') - C \sqrt{\mathbb{E}_{s \sim d^{\pi_k}} \left[D_{KL}(\pi' || \pi_k)[s] \right]}$$

6: **end for**

Issues are :

- ▶ C is quite high when γ is close to 1 $\left(C = \frac{4\varepsilon\gamma}{1-\gamma^2} \alpha^2 \right)$
- ▶ Consequently, step size becomes too small

Majorize Maximize Framework

Majorize-Maximize framework is used to solve the optimization step

- ▶ Instead of KL penalty, use KL constraint
- ▶ Can control worst case error through constraint upper limit

$$\pi_{k+1} = \arg \max_{\pi'} [L_{\pi_k}(\pi')]$$
$$\text{such that } \mathbb{E}_{s \sim d^{\pi_k}} D_{KL}(\pi' || \pi_k)[s] \leq \delta$$

- ▶ From the constraint, **steps respect a notion of distance in policy space**
- ▶ Above constrained optimization is basis of many algorithms, Natural Policy Gradient (NPG), truncated NPG, TRPO and PPO
- ▶ The objective and the constraint can be estimated from the roll-out of old policies – **sample efficient**
- ▶ Update is parametrization invariant
